

## Rule L: Dominated Transition

Rule L removes transitions that have the same effect as another transition, but with more preconditions. Since both transitions lead to the same state, we can therefore remove the one with the higher preconditions and use the other instead. See the formal description in Figure 1.

Precondition	Update
Fix transition $t_1$ and $t_0$ s.t.:	
L1) $I(t_1) \geq I(t_0)$	UL1) Remove $t_0$
L2) $\Xi(t_1) \leq \Xi(t_0)$	
L3) $E(t_1) = E(t_0)$	

Figure 1: Rule L: Dominated Transition

**Theorem 1** *Rule L in Figure 1 is correct for CTL\*.*

## Rule M: Effectively dead places and transitions

The Rule M finds and removes effectively dead places and transitions. We define an effectively dead place to be a place that will never gain nor lose tokens. Effectively dead transitions are transitions that are initially disabled (and/or inhibited) by a place that cannot gain (and/or lose) tokens. These places and transitions are found using fixed-point iteration as defined in Algorithm 1.

---

### Algorithm 1: Rule M: Effectively dead places and transitions

---

**Input:** A net  $N = \langle P, T, \Xi, \Theta, I \rangle$ , initial marking  $M_0$  and CTL\* formula  $\varphi$

**Output:** A reduced net  $N'$  and its initial marking  $M'_0$

```

1  $S_{\leq} := P$                                 /* Places that cannot gain tokens */
2  $S_{\geq} := P$                                 /* Places that cannot lose tokens */
3  $F := T$                                     /* Transitions that cannot fire */
4 do
    |   /* Find transitions that may fire and update sets
    |   accordingly */
5   foreach  $t \in F$  where
    |    $\forall p \in P. (\Xi(p, t) \leq M_0(p) \vee p \notin S_{\leq}) \wedge (I(p, t) > M_0(p) \vee p \notin S_{\geq})$ 
    |   do
6   |    $F := F \setminus \{t\}$ 
7   |    $S_{\leq} := S_{\leq} \setminus t^{\Theta}$ 
8   |    $S_{\geq} := S_{\geq} \setminus \Xi t$ 
9 until  $S_{\leq}$ ,  $S_{\geq}$ , and  $F$  do not change
10  $P' := P \setminus (S_{\leq} \cap S_{\geq} \setminus \text{places}(\varphi))$ 
11  $T' := T \setminus F$ 
12 return  $N' = \langle P', T', \Xi, \Theta, I \rangle$  and  $M_0$ 
```

---

**Theorem 2** *Rule M in Algorithm 1 is correct for CTL\*.*

**Theorem 3** *Rule M supercedes Rule E.*

## Rule N: Redundant arc removal

The lower bound number of tokens at a place  $p_0$  is given by the minimum of the initial marking and the number of tokens returned by any consuming transition with a negative effect on  $p_0$ . Using the lower bound we can then find transitions, which are never disabled by  $p_0$  and remove the transition's dependency on  $p_0$ , since it is unnecessary, as long as we maintain the effect of firing the transition.

Precondition	Update
Fix place $p_0$ and transition $t_0$ s.t.:	
N1) $t_0 \in p_0^\bullet \setminus p_0^\boxminus$	UN1) Set $\boxplus(p_0, t_0) := \boxplus(p_0, t_0) - \boxminus(p_0, t_0)$
N2) $\boxminus(p_0, t_0) \leq low$	UN2) Set $\boxminus(p_0, t_0) := 0$
where	
$low = \min\{M_0(p_0)\} \cup \{\boxplus(p_0, t) \mid t \in p_0^\boxminus\}$	

Figure 2: Rule N: Redundant arc removal

**Theorem 4** *Rule N in Figure 2 is correct for CTL\*.*

## Rule O: Inhibited transition

We can find the lower bound of tokens at a place  $p_0$ . Any inhibitor arc from  $p_0$  with a weight smaller than the lower bound always inhibits the given transition, which means that the transition can be removed. See Figure 3 for a formal description of Rule O.

Precondition	Update
Fix place $p_0$ and transition $t_0$ s.t.: O1) $t_0 \in p_0^\circ$ O2) $I(p_0, t_0) \leq low$ where $low = \min\{M_0(p_0)\} \cup \{\boxplus(p_0, t) \mid t \in p_0^\boxminus\}$	UO1) Remove $t_0$ .

Figure 3: Rule O: Inhibited transition

**Theorem 5** *Rule O in Figure 3 is correct for CTL\**

## Rule P: Redundant inhibitor arc

Sometimes we can find an upper bound on the number of tokens at a place  $p_0$ . This upper bound is given by the initial marking if all transitions have a non-positive effect on  $p_0$ . Any inhibitor arc from  $p_0$  with a weight higher than the upper bound of  $p_0$  therefore never inhibits, which means the inhibitor arc can be removed. See Figure 4 for a formal description of Rule P.

Precondition	Update
Fix place $p_0$ and transition $t_0$ s.t.: P1) $t_0 \in p_0^\circ$ P2) $I(p_0, t_0) > M_0(p_0)$ P3) $\boxplus p_0 = \emptyset$	UP1) $I(p_0, t_0) = \infty$ .

Figure 4: Rule P: Redundant inhibitor arc

**Theorem 6** *Rule P in Figure 4 is correct for CTL\*.*

## Rule Q: Preemptive transition firing

Rule Q evaluates transitions that are initially enabled and are the only consumer of all places in its pre set. The formal description of Rule Q can be found in Figure 5. Remark that Rule Q can potentially put tokens into places which will prevent other reductions. Furthermore, it can be applied infinitely if  $\Xi(t_0) \leq \boxplus(t_0)$ , or if the Petri net contains a loop.

Precondition	Update
Fix transition $t_0$ s.t.: Q1) $(\bullet t)^\bullet = \{t_0\}$ Q2) $\Xi(t_0) \leq M_0 < I(t_0)$ Q3) $(\bullet t_0 \cup t_0^\bullet) \cap places(\varphi) = \emptyset$ Q4) $(\bullet t_0)^\circ = (t_0^\bullet)^\circ = \emptyset$	UQ1) $M_0 := M_0 + E(t_0)$ .

Figure 5: Rule Q: Preemptive transition firing

**Theorem 7** *Rule Q in Figure 5 is correct for  $CTL \setminus X$ .*

## Rule R: Atomic post-agglomerable producer

Rule R is similar to a post agglomeration rule and a formal description of Rule R is in Figure 6. In Rule R we look for a place  $p_0$  with a producer  $t_0$  such that  $t_0$  can always be followed by a firing of any consumer of  $p_0$  without inhibiting other transitions or affecting places in  $places(\varphi)$ . The producer  $t_0$  is then replaced with new transitions, one for each consumer, and these new transitions combine the effect of firing  $t_0$  and the given consumer. Similarly to an agglomeration rule, Rule R removes interleavings despite potentially increasing the size of the Petri net. However, Rule R is more general, since it only operates on one producer at a time and leaves  $p_0$  untouched, allowing tokens in  $p_0$  in the initial marking, which a post agglomeration does not. Additionally, Rule R does not require the weights of the arcs to and from the agglomerated place to be equal, making R usable in many cases.

**Theorem 8** *Rule R in Figure 6 is correct for  $LTL \setminus X$ .*

Precondition	Update
Fix place $p_0$ and transition $t_0$ s.t.: R1) $t_0 \in \bullet p_0 \wedge p_0^\bullet \neq \emptyset$ R2) $\bullet p_0 \cap p_0^\bullet = \emptyset$ R3) $p_0^\circ = {}^\circ(p_0^\bullet) = ((p_0^\bullet)^\bullet)^\circ = \emptyset$ R4) $(\{p_0\} \cup (p_0^\bullet)^\bullet) \cap places(\varphi) = \emptyset$ R5) $\bullet(p_0^\bullet) = \{p_0\}$ R6) $\boxplus(t_0, p_0) \geq \boxminus(p_0, t)$ for all $t \in p_0^\bullet$	UR1) For each transition $t \in p_0^\bullet$ create a transition $\langle t_0 t \rangle$ with the following arcs: $\boxminus(\langle t_0 t \rangle) = \boxminus(t_0)$ $\boxplus(\langle t_0 t \rangle) = \boxplus(t_0) + \boxplus(t) - \boxminus(t)$ $I(\langle t_0 t \rangle) = I(t_0)$ UR2) Remove $t_0$

Figure 6: Rule R: Atomic post-agglomerable producer
